Abstract

Backgrounds: Oral mucositis is a frequent adverse side effect of cancer chemotherapy which is associated with intense oral pain. However, it impairs the quality of life of these patients. Low Level Laser Therapy (LLLT) has been increasingly used in recent years, mostly to accelerate wound healing and to reduce pain. In cancer patients, LLLT has been shown to reduce the incidence and severity of oral mucositis. **Objectives:** The aim of this study is to evaluate the effect of low level laser therapy in the management of chemotherapy induced oral mucositis. **Patients and Methods:** The study design used was a randomized clinical trial. A total of 67 cancer patients were eligible to participate in the study. Thus, they were divided randomly into two groups: group 1 irradiated with prophylactic or active laser therapy (AlGaInAs laser diode device with a wave length of $940 \pm 15 \text{nm}$, 0.3mW , and a probe emitting dose of 4.2J/cm^2) and group 2 received inactive or sham laser therapy (power output equal to zero). However, for the ethical purpose, once the patients developed ulcerative mucositis, they are irradiated with active laser therapy. The oral assessment was performed daily starting from the first day of the chemotherapy by

applying WHO grading system. After 24 hours, the assessment of associated oral pain was carried out every two days with visual analog scale before laser application. Consequently, the associations between variables were analyzed statistically using SPSS version 20. **Results:** All the patients were presented with some grade of oral mucositis. In the active or prophylactic laser group, the severity of oral mucositis was lower than the inactive or therapeutic laser group. Moreover, the incidence of grade 3 and grade 4 were less observed in the active or prophylactic laser groups than the sham or therapeutic laser groups. In addition, the mean time of healing was significantly lower in the prophylactic laser group than in the therapeutic laser groups (2.05 + 1.89 versus 4.5 + 2.4 days, $p > 0,004$). Prophylactic laser application was associated with significant reduction of oral pain in comparison with inactive or therapeutic laser therapy (1.18 + 1.09 versus 2.12 + 1.60, $p > 0.01$). **Conclusions:** Prophylactic laser therapy is effective in reducing the incidence of severe oral mucositis and in alleviating associated oral pain.

Keywords: Low level laser Therapy, oral mucositis, chemotherapy, cancer patient

Introduction

Despite considerable improvement in the medical management of cancer patients in recent years, significant complication often accompanies the potential benefits of the treatment. Chemotherapy induced oral mucositis is a frequent oral complications achieved in patients which receives highly mucotoxic drugs (Arora *et al.*, 2008; Sonis, 2009; Ramírez-Amador *et al.*, 2010; Freitas *et al.*, 2014)

Oral mucositis is associated with intense pain which limits patient's ability to eat and drink normal foods (Silverman, 2007). Severe and wide spread ulcerated mucositis in these group of medically compromised patients both physiologically (by the tumour) and literally (by cancer therapy) will place them at an increased risk of systemic infection and bleeding (Bensadoun, 2012; Sonis, 2009). Consequently, the quality of life of these patients will be greatly compromised (Nes and Posso, 2005; Abramoff *et al.*, 2008).

The literature review revealed that various pharmacological and non-pharmacological agents have tried to prevent and/or treat oral mucositis. Thus, they have made the subject of mucositis to be one of the most researched field explored in supportive care in cancer by many researchers (Sandoval *et al.*, 2003; Sonis, 2009; Gouvea de Lima *et al.*, 2012).

Among the various agents being investigated is the Low Level Laser Therapy (LLLT). Laser therapy is a photomedicine procedure proposed to

exert beneficial effect in inflammatory conditions like rheumatoid arthritis (Bensadoun and Nair, 2012; Ekim *et al.*, 2007).

Even though the precise molecular mechanism to explain their activity are not clearly evident, however, it has been suggested that LLLT will promote wound healing (Volpato *et al.*, 2009). Also, it was observed that LLLT will induce biological changes in the epithelial and connective tissues through the stimulation of rapid epithelization and regeneration of myofibroblast originating from the fibroblast (Chaves *et al.*, 2014).

Moreover, low power laser have also been reported to exert pain relief potential through the modification of nerve conduction via the release of endorphins and enkephalines (Jaguar *et al.*, 2007).

In addition to these effects, low intensity laser therapy have been investigated to prevent and/or treat oral mucositis due to radiotherapy (Arora *et al.*, 2008; Gouvea de Lima *et al.*, 2012; Gautam *et al.*, 2012; Carvalho *et al.*, 2011); chemotherapy (Nes and Posso, 2005; Abramoff *et al.*, 2008; Cruz *et al.*, 2007; Kuhn *et al.*, 2009); and in Hematopoetic Stem Cell Transplantation (HSCT) (jaguar *et al.*, 2006; Silva *et al.*, 2011).

Low level laser therapy has not been studied for cancer patients undergoing chemotherapy in our country. Accordingly, we performed a double blind randomized study to investigate the clinical effect of low level laser therapy in the management of chemotherapy induced mucositis.

Patients and Methods

The Study Design and Patient Characterization

The study was designed as a double blind randomized clinical trial. The samplings were carried out in Hiwa Hospital in Sulaimani city (Northern east of Iraq) from June 2013 to September 2014. Eligible patients were all consecutive cancer patients receiving chemotherapy with the following inclusion and exclusion criteria.

Inclusion Criteria

- Pediatric and young adult patients utilizing intensive mucotoxic chemotherapy (single highly mucotoxic drug or combination of two or three intensive chemotherapeutic regimen).
- Patients who stay in hospital for at least 21 days.
- Patients who agreed to participate in the study.

Furthermore, in exclusion criteria, patients were withdrawn from participation according to their request or due to loss in follow up, those who miss three consecutive day treatments, and those with unstable clinical condition.

Before conducting the study procedure, the institutional Ethics Committee approved the protocol. However, all the procedures were

performed in accordance with applicable guidelines of Good Clinical Practice and the Declaration of Helsinki. Written informed consent was obtained from all patients or their parents before they were enrolled into the study procedure.

Prophylactic Laser Application

Sixty seven patients met the inclusion and exclusion criteria and they were randomly divided into two groups using a block randomization with a manual schedule: group A (active laser) and Group B with sham (inactive laser). In addition, patients were blinded towards the therapeutic protocol of their groups.

Laser irradiation were performed with iLase™ (BIOLASE, Inc., Irvine, CA92618 USA, with a wave length of $940\pm 15\text{nm}$, output power 0.3 mW “Pulse Mode”, continuous infrared AlGaInAs diode) Laser.

Patients who participated in the active and passive laser groups were irradiated daily for three successive weeks starting from the day of the chemotherapy course. At each treatment sessions, ten anatomic sites (the right and left hand side of the cheeks, lower and upper labial mucosa, ventral and lateral tongue, floor of the mouth and anterior tonsillar pillars) of the oral cavity were illuminated for 30s.

All the procedure were performed by a single oral medicine specialist, after adjustment of the iLase™ device for soft tissue pathology (i.e aphthus ulceration mode). Thus, the power output was reduced to 0.3 mW. This initiated an energy power of 4.2 J/cm^2 when the probe were held at about 7-8mm away from the oral mucosal surfaces

In the active or prophylactic group, patients were irradiated with the probe emitting dose of 4.2 J/cm^2 . Also, participants in the sham or inactive laser group were irradiated with the same, but inactive probes. For ethical purpose, once the patients establish a ulcerated mucositis, they are irradiated with therapeutic active laser therapy. During irradiation procedure, the patients and the therapist wear goggles to avoid retinal exposure to laser light. Thus, the procedure was carried out in the morning between 9-11pm.

Lastly, all the patients underwent hospital stander oral mucositis prophylactic measure in the form of Italian solution (A mixture of vit. B complex, Folic acid, Normal saline, Mycostatin drop, Hydrocortisone, NaHCO_3 (Sodium bicarbonate), and Lidocaine ampule).

Clinical Evaluation of Oral Mucositis

Patients were assessed for response to laser therapy on a daily basis by employing WHO grading system by specialized independent hematologist who was blinded regarding the studied groups. The evaluation for the

development of ulcerative oral lesion and the time needed for healing were also recorded clinically.

Oral Pain Evaluation

Subjective evaluation of oral pain was performed every two days after receiving chemotherapy using a Visual Analog Scale (VAS), in which “0” represent the absence of pain and “10” represent the worst severe pain felt by the patient. Consequently, the Wang-baker Faces pain rating scale were used for oral pain in pediatric patients who were not able to rate their oral pain in response to laser therapy.

Statistical Analysis

All data were analyzed using SPSS (version 20 software) computer program. Statistical analysis used in this study included descriptive statistics for the evaluation of age, sex, types of tumour, and types of chemotherapy. For quantitative variables like pain score and the time of healing, the univariate analysis which included t test and Mann-Whitney U test were applied. The differences between the studied groups were analyzed by adopting Chi-square test and fisher exact test for qualitative variables. The strength of association was also examined using risk ratio. All p values were based on 2-sided tests and $p < 0.05$ was considered to be statistically significant.

Results

A total of 67 patients were consecutively enrolled in the study between June 2013 and September 2014. Patient’s characterization, tumor types, and chemotherapy regimen are listed in Table 1. The majority of the participants were male and most of the patients were diagnosed with hematological malignancies. The most frequent types of chemotherapy regimen was Methotrexate based regimen in the sham laser group, while Etoposide based regimen was most popular in the active laser group of patients.

Table 1: General characteristics of studied patients

Characteristics	Active Laser No. = 34	Sham Laser No. = 33
Age (year), mean \pm SD	15.6 \pm 12.0	14.8 \pm 7.8
Sex, No. (%)		
Male	20 (58.8)	21 (63.6)

Evaluation of Oral Mucositis

All patients in both groups were presented with some grade of oral mucositis. Although the daily evaluations of oral mucositis revealed no statistically significant difference between the studied groups (Table 2), however, the incidence of grade 3 and grade 4 were less observed in the active or prophylactic laser groups than sham or therapeutic laser groups (figure 1). Moreover, the risk ratio for developing different grades of oral mucositis was considerably increased in sham laser groups than active laser groups reaching about RR=2.8 for the occurrence of both grade 3 and grade 4 oral mucositis (Table 3).

Table 2: Daily evaluation of oral mucositis in the studied groups according to WHO scoring system

Figure 1: The incidence of oral mucositis throughout the study periods in both groups (active laser and sham laser). Note: No significant difference between the percentage of grades (1, 2, 3, and 4) in active laser and sham laser, P> 0.05.

Table 3. Estimation of Risk ratio for the development of different grades of oral mucositis between sham and active laser groups

WHO Grades	Risk Ratio (RR)
RR (grade 1) Sham/active	1.2
RR (grade 2) Sham/active	1.8
RR (grade 3) Sham/active	2.5
RR (grade 4) Sham/active	5
RR (grade 3 & 4) Sham/active	2.8

Time of Healing Oral Mucositis

There was a significant difference between the studied groups. Therefore, the mean time of healing in the active laser groups was 2.05 ± 1.89 day, while for the sham laser groups was 4.5 ± 2.4 days (i.e. patients who received prophylactic active laser therapy requires less time for healing in the established oral mucositis than patients who received therapeutic sham laser therapy as shown in table 4).

Table 4. Mean time of healing in patients received active laser and sham laser

Time of healing (day)		P value
Mean \pm SD		
Active laser	Sham laser	
2.05 \pm 1.89	4.5 \pm 2.4	0.004

Pain Score

The proportion of patients presented with oral pain remained insignificant between the studied groups throughout day 6 and 8. Thus, significant differences were observed in the following days (table 5). Furthermore, the mean value for pain score were kept minimal between the studied groups with statistically significant difference (i.e prophylactic and therapeutic application of low level laser therapy were associated with the reduction of subjective feeling of oral pain; details are shown in table 6).

Table 5: Mann-Whitney U for difference in pain score in studied groups

Days of treatment	Pain score		P value
	Median(range)		
	Laser	Sham	
Day 6	0 (0 – 3)	0 (0 – 3)	-
Day 8	1.5 (0 – 7)	2 (0 – 7)	0.458
Day 10	2 (0 – 8)	4 (0 – 7)	0.051
Day 12	2.5 (0 – 8)	4 (0 – 9)	0.032
Day 14	0 (0 – 5)	3 (0 – 9)	0.008
Day 16	0 (0 – 4)	2 (0 – 7)	0.001
Day 18	0 (0 – 3)	0 (0 – 5)	-
Day 20	0 (0 – 3)	0 (0 – 5)	-

Discussion

Patients undergoing chemotherapy and radiotherapy for the treatment of malignant neoplasm often developed oral mucositis as an adverse side effect of their treatment. Indeed, oral mucositis regarded as a major debilitating and distressing complication often accompanies bone marrow transplantation (Abramoff *et al.*, 2008).

Table 6: Mean pain score value between the group of active laser and sham laser

Study group	Average pain score	P value
	Mean \pm SD	
Active laser	1.18 \pm 1.09	0.010
Sham laser	2.12 \pm 1.60	

Oral mucositis can severely impacts the quality of life of these individuals and may necessitate cancer treatment cessation or interruption which consequently may results in reduced control of local tumor followed by an increased morbidity and mortality. Furthermore, cancer treatment discontinuation also increases the cost and duration of the treatment and prolongs the time of hospitalization (Nes and Posso, 2005).

Various pharmacological and non pharmacological agents have tried in preventing and treating oral mucositis. Despite some positive outcomes, it has not been proven to be completely effective in preventing oral mucositis on its own. Till now, there are no single intervention acts on all phases of oral mucositis (Bjordal *et al.*, 2011).

Low Level Laser Therapy (LLLT) is a local application of a non-chromatic. However, narrow-band coherent light source used for the photostimulation of biological tissue is recommended as a treatment options for oral mucositis (Abramoff *et al.*, 2008; Bjordal *et al.*, 2011).

The concept behind the application of laser therapy in the management of oral mucositis is that low power lasers induce anti-inflammatory action and accelerate wound healing by increasing the vascularity and reepithelization. In addition, Lopes *et al.* (2009) showed that low power laser appears to decrease the severity of oral mucositis, at least in part, by reducing the COX-2 levels which in turn affect the pathophysiology of oral mucositis (Sonis *et al.*, 2004).

Moreover, recent publication from the Multinational Association for Supportive Care in Cancer (MASCC) and the International Society of Oral Oncology (ISOO), recommended the administration of LLLT in patients receiving HSCT, conditioned with high dose chemotherapy with or without total body irradiation (Lalla *et al.*, 2014; Oberio *et al.*, 2014).

From this point of view, the present study aimed to evaluate the impact of LLLT in the management of chemotherapy induced oral mucositis. For this purpose, we conduct a prospective randomized clinical trial in 67 cancer patients receiving intensive mucotoxic drugs at high risk of developing oral mucositis.

Our data showed no statistically significant difference between the studied groups in terms of the incidence of oral mucositis. Subsequently, the active or the prophylactic laser group presented less severe mucositis (grade 3 and grade 4) than the sham or curative laser group.

This finding is fairly consistent with the outcomes of other investigators and confirms the advantages of using phototherapy in controlling signs and symptoms of oral mucositis in patients undergoing cancer chemotherapy (Freitas *et al.*, 2014; Abramoff *et al.*, 2008; Arbabi-Kalati *et al.*, 2013) or patients receiving radiotherapy (Carvalho *et al.*, 2011; Arora *et al.*, 2008).

Similarly, Cown *et al.* (1997) and Jaguar *et al.* (2007) also found a reduction in the progression of severe mucositis using laser illuminations in patients who are receiving conditioning regimen for HSCT.

In contrast, Gouvea de Lima *et al.* (2012) revealed that LLLT was not effective in reducing the incidence of severe grades of oral mucositis (grade 3

or 4) in head and neck cancer patients undergoing concurrent chemoradiotherapy.

In this present work and for ethical reasons, once the patients presented with ulcerated mucositis, they underwent curative laser therapy. Although the reason is not entirely understood, curative laser application seems to be less successful than prophylactic laser administration. This might explain the high risk ratio for developing severe ulcerative mucositis (grade 3 and grade 4) in the curative (sham) laser group than prophylactic (active) laser group in the present work.

In addition, other researchers also confirmed the superiority of prophylactic laser application than therapeutic methods (Carvalho *et al.*, 2011; Arora *et al.*, 2008). Furthermore, in their meta analysis, Oberio *et al.* (2014) demonstrated that local application of laser therapy will reduce the overall risk of severe mucositis and other measures of mucositis severity including the duration of severe mucositis and related oral pain.

Contrary to our results, Cruz *et al.* (2007) did not find any evidence on the benefit of the preventive use of low level laser therapy in children and adolescents with cancer that are treated with chemotherapy. However, one plausible cause for the conflicting results may be due to the involvement of children and adults with cancer in the current study, and the patients were evaluated on a daily basis. Cruz *et al.* (2007) carried out their evaluation weekly on day 1, 8, and 15 after chemotherapy. So, overestimation may be noticed by the authors or the authors may also point to the possibility of a protective effect of the rigorous oral hygiene carried out in all the participants previously and during the study preparation.

The time of healing and the duration of severe mucositis was significantly lower in the active (prophylactic) laser group than sham (curative) laser group, which showed agreement with the previous reports declared by Oberio *et al.*, 2014; Volpato *et al.*, 2009; and Bensadoun and Nair, 2012.

From the patient's perspective, subjective feeling of pain is the most distressing side effect of oral mucositis. This is because it interferes with the ability to eat, drink, swallow, and speak. Also, it results in an increase in the amount of analgesic administration and parenteral nutrition. Our observation demonstrates a statistically significant reduction in the time of oral pain in the active laser group in comparison to the curative or sham laser group. Interestingly, the pain score in the sham laser group was also reduced and did not exceed $2.12 + 1.60$. Moreover, the mean pain score was reduced in the active laser group than in the sham laser group.

The inference of the study results clearly indicate that the reduction of oral pain experience was the most remarkable effect of LLL therapy reported by our patients. Therefore, this fact was accepted by many

investigators in the literature (Bensadoun *et al.*, 1999; Cown *et al.*, 1997; Nes and Posso, 2005; Jaguar *et al.*, 2007; Schubert *et al.*, 2007; Abramoff *et al.*, 2008; Gautam *et al.*, 2012).

However, Gouvea de Lima *et al.* (2012) and Wong and Wilder-Smith (2002) presented different data. The former showed that the oral pain between placebo and the treated group with laser device does not differ considerably in head and neck cancer patients receiving chemoradiotherapy. Furthermore, the latter reported lack of any statistically significant difference in pain scores at baseline and weekly, thereafter (except in 1 patient) in patients receiving chemotherapy.

However, it is often difficult to compare their study results with the present study, taking into consideration the difference between radiation induced and chemotherapy induced mucositis. In addition, the diverse parameters and different laser device applied in their study may address the discrepancy of their results with ours.

In conclusion, our findings relates well to the emerging LLLT evidence in preventing oral mucositis and reducing the severity and potential pain related to this conditions. It is also interesting to note that the variety of cancer chemotherapies administered by our patients did not seem to seriously interfere with the beneficial effects of LLLT. Furthermore, the device was well tolerated and no serious incidents or withdrawal due to treatment intolerance were reported by our patients.

Consequently, low power laser should be target for future trials to compare treatment start at different time points before cancer therapy to avoid unnecessary LLLT exposure.

Acknowledgements

The authors would like to thank the doctors and staffs of Hiwa Hospital in Sulaimani city, especially Dr. Basil K Abdulla and Dr. Banaz Mubarak for their kind cooperation in the selection of the patients.

The authors would also like to thank Assistant Professor Dr. Laith Alrudainy for his help in the statistical analysis.

Great thanks also go to Dr. Tamara Al-Karadaghi for her help regarding the laser device adjustment.
